

Frames and Window Handling in Selenium

Master frame switching, returning to the main page,
and managing **multiple windows** with confidence.

Presented by
Swathi

Introduction

Selenium enables **automated testing** of web applications

Web applications commonly use **frames and multiple windows**

Effective handling of frames and windows is essential for **reliable automation**

Selenium provides built-in methods to **switch, manage, and return** seamlessly

Frame Handling

A frame is a **section inside** a web page.

Selenium must **switch to the frame** to access elements inside it.

Once switched, you can **interact** with elements within that frame.

Switching back returns you to the **main page context**.

```
driver.switchTo().frame(0);
```

Returning to Main Page

After working inside a frame,
shift focus back to the main page.

```
driver.switchTo().defaultContent():
```

Window Handling

Window handling is used to manage **multiple windows or browser tabs**.

Each window has a unique **Window ID**.

Important Methods

essential selenium methods for [window handling](#)

01

Current Window ID

`driver.getWindowHandle();`

02

All Window IDs

`driver.getWindowHandles();`

03

Switch to Another Window

`driver.switchTo().window(windowoidl);`

Frame vs Window

FRAME

A section inside a web page

Handle using `switchTo().frame()`

VS

WINDOW

A separate browser window or tab

Handle using `switchTo().window()`

Conclusion

Mastering frames and window handling makes selenium automation **complete** and **reliable**.

Frames let you work with content inside a page

Windows let you manage multiple tabs or windows

Together, they ensure **accurate** and **stable** automation

Thank You

Thank you for your **time and attention**.

I appreciate your **engagement** throughout the session.

Questions and discussions are **welcome**.

Let's keep building **reliable automation** together.
